

Pablo Lara

For this project, I worked on completing my part of the Module 2 lab using Google Colab. This was my first time using Colab, so at first I was not really sure what I was doing or what all the different tools were for. I worked through the notebook one section at a time and ran the code to make sure everything was working.

As I worked through the lab, I used pandas, NumPy, and matplotlib. I am still learning what each one does, but this project helped me understand them better because I could actually see them being used together. I worked with the Iris data, looked at the information in the tables, and went through the different graphs and calculations.

The scatter plot was one of the harder parts for me because at first I did not really understand what I was looking at. The bar graph made more sense to me because I could clearly see that there were 50 samples for each flower species. Going through both helped me understand why different types of graphs can be useful when looking at data.

I also completed the calculations and written questions that were part of my notebook. Once I finished, I ran the notebook again to make sure everything worked and saved my completed work for the project.

For the group portion, I uploaded my own files to our GitHub repository. I created my own branch and pull request so that my work could be identified separately from the other group members' work.

Overall, my contribution to the project was completing my own Module 2 lab, checking that it worked correctly, completing my reflection and contribution documents, and adding my work to the group GitHub

Marlon Roberts

What I Did:

- 1.Created a GitHub
- 2.Invited my team members
- 3.As the Author I created a file so everyone can access into, pulling and merging.
- 4.created a google Collab and accessed the lab notes.
- 5.Ran through cell notebooks and learned what they were.
- 6.went through all 16 cells and wrote my reflections.
- 7.Checked the wok on the dataset
- 8.before exporting my file I ran run time
- 9.exported my file to GitHub
- 10.submit files to canvas
11. I created data visualizations using matplotlib
12. Learned about NumPy arrays, data manipulation, pandas data frames

Brandy Gonzales

The group shared a GitHub repository for the Module 02 lab deliverables. What I contributed: *
Opened the team lab notebook after it was added to the shared repo and worked through it in
Google Colab. * Ran the notebook cells (including NumPy mean/standard deviation and the
species bar chart visualizations) and checked that outputs appeared. * Reviewed and rewrote the
analysis/reflection markdown in my own words so the documentation reflected my
understanding (dataset overview, key findings, questions short reflection). * Exported the
completed notebook to PDF from Colab (Print-> Save as PDF) * Wrote a separate Reflective
Journal PDF about what I learned from pandas, NumPy, matplotlib, and the Iris scatter plot. *
Uploaded my deliverable file to the shared GitHub repository after receiving push access. * Will
submit the shared repository URL in Canvas What teammates handled: * Initial shared repository
setup and uploading the start lab notebook for the group. Notes: * I completed my notebook run
and written work independently. Collaboration was limited to using the shared GitHub repo for
depositing files. * My GitHub commit history on the shared repo should show my uploads as
proof of contribution.

Derrick K. Gibbs-McGlaston

For this project, I completed my assigned portion of the Module 2 Lab Exercise independently. I worked through the Google Colab notebook and completed the required activities involving pandas, NumPy, matplotlib, and the Iris dataset. I loaded and examined the Iris dataset and converted the dataset into a pandas DataFrame for analysis. I reviewed the structure of the dataset, including the number of samples, features, and classes. I also used pandas to calculate the mean measurements for each iris species and determine the number of samples belonging to each species. I completed the NumPy exercise by calculating the mean and standard deviation of the sepal length measurements. I verified the results using the notebook's built-in checks and confirmed that the calculations executed successfully. I completed the data visualization exercises using matplotlib. I created a scatter plot comparing sepal length and sepal width by iris species and created a bar chart showing the number of samples for each species. I reviewed the visualizations to identify patterns and differences among the three classes. I also completed the required analysis and reflection section of the notebook. I documented observations about the dataset, identified questions for further investigation, and reflected on what I learned about using pandas, NumPy, and matplotlib as part of a machine learning workflow. After completing the notebook, I ran the cells to verify that the code executed successfully and that the required outputs and visualizations were displayed correctly. I also exported the completed notebook as a PDF. Summary of Contribution My individual contribution consisted of completing the Module 2 laboratory exercises, analyzing the Iris dataset, performing the required numerical and data operations, creating and interpreting visualizations, completing the required notebook documentation and reflection, testing the notebook, and exporting the completed notebook as a PDF. The GitHub repository and upload of the completed notebook were handled by another group member and are therefore not included as part of my individual contribution.

Victor Djuma

My Individual Contribution For Module 2, my individual contribution focused on completing and verifying the machine learning development tools lab in Google Colab. I worked through all 16 notebook cells and made sure the code was executed successfully before moving forward. I used the Iris dataset while working with pandas, NumPy, and Matplotlib, and I checked the outputs produced by the notebook. A major part of my work was reviewing data and visualizations. I practiced using pandas DataFrames to organize the dataset, used NumPy for numerical calculations, and examined the graphs created with Matplotlib. NumPy and interpreting the graphs were the most challenging parts for me, so I spent extra time connecting the code to the results shown in the outputs. After completing the notebook, I ran the work again to make sure the outputs and visualizations were visible and reproducible. I then exported the completed notebook as a PDF and checked that the code, outputs, and graphs could be read clearly. I also completed my personal Reflection Journal, focusing on what I learned and the areas that were difficult for me. My contribution to the group project is my own completed Module 2 lab work and documentation. I am responsible for providing my completed notebook, notebook PDF, Reflection Journal, and this Individual Team Member Contribution Journal for the team Git repository. This journal documents only the work I personally completed for this assignment.
